# MAS352/61023 – Formula Sheet – Part One

Where not explicitly specified, the notation used matches that within the typed lecture notes.

### Modes of convergence

- $X_n \xrightarrow{d} X \iff \lim_{n \to \infty} \mathbb{P}[X_n \le x] = \mathbb{P}[X \le x]$  whenever  $\mathbb{P}[X \le x]$  is continuous at  $x \in \mathbb{R}$ .
- $X_n \xrightarrow{\mathbb{P}} X \iff \lim_{n \to \infty} \mathbb{P}[|X_n X| > a] = 0$  for every a > 0.
- $X_n \stackrel{a.s.}{\to} X \iff \mathbb{P}[X_n \to X \text{ as } n \to \infty] = 1.$
- $X_n \xrightarrow{L^p} X \iff \mathbb{E}\left[|X_n X|^p\right] \to 0 \text{ as } n \to \infty.$

### The binomial model and the one-period model

The binomial model is parametrized by the deterministic constants r (discrete interest rate),  $p_u$  and  $p_d$  (probabilities of stock price increase/decrease), u and d (factors of stock price increase/decrease), and s (initial stock price).

The value of x in cash, held at time t, will become x(1+r) at time t+1.

The value of a unit of stock  $S_t$ , at time t, satisfies  $S_{t+1} = Z_t S_t$ , where  $\mathbb{P}[Z_t = u] = p_u$  and  $\mathbb{P}[Z_t = d] = p_d$ , with initial value  $S_0 = s$ .

When d < 1 + r < u, the risk-neutral probabilities are given by

$$q_u = \frac{(1+r)-d}{u-d}, \qquad q_d = \frac{u-(1+r)}{u-d}.$$

The binomial model has discrete time t = 0, 1, 2, ..., T. The case T = 1 is known as the one-period model.

#### Stirling's Approximation

It holds that  $n! \sim \sqrt{2\pi n} \left(\frac{n}{e}\right)^n$ .

#### Conditions for the optional stopping theorem (MAS61023 only)

The optional stopping theorem, for a martingale  $M_n$  and a stopping time T, holds if any one of the following conditions is fulfilled:

- (a) T is bounded.
- (b)  $\mathbb{P}[T < \infty] = 1$  and there exists  $c \in \mathbb{R}$  such that  $|M_n| \leq c$  for all n.
- (c)  $\mathbb{E}[T] < \infty$  and there exists  $c \in \mathbb{R}$  such that  $|M_n M_{n-1}| \le c$  for all n.

# MAS352/61023 – Formula Sheet – Part Two

Where not explicitly specified, the notation used matches that within the typed lecture notes.

### The normal distribution

 $Z \sim N(\mu, \sigma^2)$  has probability density function  $f_Z(z) = \frac{1}{\sqrt{2\pi\sigma}} e^{-\frac{(z-\mu)^2}{2\sigma^2}}$ . Moments:  $\mathbb{E}[Z] = \mu$ ,  $\mathbb{E}[Z^2] = \sigma^2 + \mu^2$ ,  $\mathbb{E}[e^Z] = e^{\mu + \frac{1}{2}\sigma^2}$ .

## Ito's formula

For an Ito process  $X_t$  with stochastic differential  $dX_t = F_t dt + G_t dB_t$ , and a suitably differentiable function f(t, x), it holds that

$$dZ_t = \left\{ \frac{\partial f}{\partial t}(t, X_t) + F_t \frac{\partial f}{\partial x}(t, X_t) + \frac{1}{2} G_t^2 \frac{\partial^2 f}{\partial x^2}(t, X_t) \right\} dt + G_t \frac{\partial f}{\partial x}(t, X_t) dB_t$$

where  $Z_t = f(t, X_t)$ .

## Geometric Brownian motion

For deterministic constants  $\alpha, \sigma \in \mathbb{R}$ , and  $u \in [t, T]$  the solution to the stochastic differential equation  $dX_u = \alpha X_u dt + \sigma X_u dB_u$  satisfies

$$X_T = X_t e^{(\alpha - \frac{1}{2}\sigma^2)(T-t) + \sigma(B_T - B_t)}$$

### The Feynman-Kac formula

Suppose that F(t, x), for  $t \in [0, T]$  and  $x \in \mathbb{R}$ , satisfies

$$\begin{split} \frac{\partial F}{\partial t}(t,x) + \alpha(t,x) \frac{\partial F}{\partial x}(t,x) + \frac{1}{2}\beta(t,x)^2 \frac{\partial^2 F}{\partial x^2}(t,x) - rF(t,x) &= 0\\ F(T,x) = \Phi(x). \end{split}$$

If  $X_u$  satisfies  $dX_u = \alpha(u, X_u) dt + \beta(u, X_u) dB_u$ , then

$$F(t,x) = e^{-r(T-t)} \mathbb{E}_{t,x} \left[ \Phi(X_T) \right].$$

#### The Black-Scholes model

The Black-Scholes model is parametrized by the deterministic constants r (continuous interest rate),  $\mu$  (stock price drift) and  $\sigma$  (stock price volatility).

The value of a unit of cash  $C_t$  satisfies  $dC_t = rC_t dt$ , with initial value  $C_0 = 1$ .

The value of a unit of stock  $S_t$  satisfies  $dS_t = \mu S_t dt + \sigma S_t dB_t$ , with initial value  $S_0 > 0$ .

At time  $t \in [0, T]$ , the price  $F(t, S_t)$  of a contingent claim  $\Phi(S_T)$  (satisfying  $\mathbb{E}^{\mathbb{Q}}[\Phi(S_T)] < \infty$ ) with exercise date T > 0 satisfies the Black-Scholes PDE:

$$\begin{split} \frac{\partial F}{\partial t}(t,s) + rs \frac{\partial F}{\partial s}(t,s) + \frac{1}{2}s^2\sigma^2 \frac{\partial^2 F}{\partial s^2}(t,s) - rF(t,s) &= 0, \\ F(T,s) &= \Phi(s). \end{split}$$

The unique solution F satisfies

$$F(t, S_t) = e^{-r(T-t)} \mathbb{E}^{\mathbb{Q}}[\Phi(S_T) \mid \mathcal{F}_t]$$

for all  $t \in [0, T]$ . Here, the 'risk-neutral world'  $\mathbb{Q}$  is the probability measure under which  $S_t$  satisfies

$$dS_t = rS_t \, dt + \sigma S_t \, dB_t.$$

#### The Gai-Kapadia model of debt contagion (MAS61023 only)

A financial network consists of banks and loans, represented respectively as the vertices V and (directed) edges E of a graph G. An edge from vertex X to vertex Y represents a loan owed by bank X to bank Y.

Each loan has two possible states: healthy, or defaulted. Each bank has two possible states: healthy, or failed. Initially, all banks are assumed to be healthy, and all loans between all banks are assumed to be healthy.

Given a sequence of contagion probabilities  $\eta_j \in [0, 1]$ , we define a model of debt contagion by assuming that:

(†) For any bank X, with in-degree j if, at any point, X is healthy and one of the loans owed to X becomes defaulted, then with probability  $\eta_j$  the bank X fails, independently of all else. All loans owed by bank X then become defaulted.

Starting from some set of newly defaulted loans, the assumption (†) is applied iteratively until no more loans default.
